

How are function literals implemented?

How is `nums.foreach(println)`
implemented?

Describe repeated parameter syntax.

What makes a function literal a *closure*?

What is a function value?

Contrast closures and Java inner classes.

Pass array to a repeated parameter.

Describe tail-recursive stack traces.

Which instance of a local variable of a method, repeatedly called, will a closure capture?

Why the trailing underscore?

Assign a method or local function to a variable.

What do multiple underscores in a function literal do?

What are the limits of tail recursion?

Function literals vs. function values

What is the syntax for multiline function literals?

Why do local functions reduce boilerplate over private methods?
