

What is the basic syntax of the `data` keyword?

```
data TypeName = ValueConstructorA FieldA1 ... FieldAN | ValueConstructorB ...
```

What are value constructors, really?

What aren't they?

Functions that ultimately return a value of a data type. So the "fields" of a value constructor are really parameters.

They are **not** types.

Literals can be thought of as what?

Value constructors with no parameters.

How can you make your typeclass inherit another one?

Add deriving (OtherClass) to the end of the data declaration.

When there's only one value constructor for a type, it's common to do what?

Use the same name for the data type and the value constructor.
